

# Laboratory Characterisation of the Radar Signature of Methane Bubbles in Lake Ice

Keith Morrison

Dept. of Meteorology University of Reading k.morrison@reading.ac.uk

#### **MOTIVATION**

- Release of methane from thawing permafrost regions threatens to put vast amounts of this potent greenhouse gas into the atmosphere.
- One method of estimating the methane flux is by the observation of methane ice bubbles trapped within lake ice utilising SAR satellite imagery for pan-arctic monitoring
- Using laboratory simulations of ice bubbles, provided the opportunity to quantitatively analyse their radar signature in a carefully controlled, repeatable environment.

Report on physical configuration of methane (CH<sub>4</sub>) ebullition bubbles in lake ice, provided to inform laboratory radar reflectivity measurements from simulated bubbles.
